ABSTRACT
Bioactive phytochemical constituents in medicinal plants are sources and templates for the synthesis of new antimicrobial drugs, this study has revealed the phytochemicals present in Phyllantus amarus and Azadirachta indica. Screening of the extracts of Phyllanthus amarus and Azadirachta indica which indicates the presence of alkaloids, flavonoids, saponins, tannins, anthraquinones, terpenoids and cardiac glycosides in varying concentrations within the aqueous and methanol extracts. Flavonoids were abundant in the crude methanolic and aqueous extract of A.indica but were absent in the methanolic and aqueous extract of P.amarus. Alkaloids were also abundantly present in the crude methanol and aqueous extract of A.indica but were significantly absent in the crude methanol and aqueous extract of P.amarus. Saponins were slightly and moderately present in the methanol and aqueous crude extract of P.amarus while it was slightly present in both the crude methanol and aqueous extract of A. indica. Tannins were not detected in the crude methanol extract of P.amarus but were moderately present in the aqueous extract while it was slightly and moderately present in the crude aqueous and methanol extract of A.indica. Anthraquinones were slightly present in the crude aqueous and methanol extract of both P.amarus and A.indica. Terpenoids were not detected in the crude methanol extract of P.amarus but was slightly detected in the crude aqueous extract and in both the crude methanol and aqueous extract of A.indica. Cardiac glycosides were absent in the crude aqueous and methanol extract of P.amarus and A.indica.

Keywords: Aqueous, Phytochemicals, Extract and Flavonoids.

1. INTRODUCTION
Most plants contain several compounds with antimicrobial properties for protection against aggressor agents, especially microorganisms. Active compounds found in some plants have antiseptic action; for example, thyme has thymol and carvacrol, clove has eugenol and isoeugenol, and oregano has carvacrol and terpinenol-4. In some cases, terpenes from essences that are soluble in water have higher antibacterial power than others (Knobloch et al., 1989). The plant chemicals are classified as either primary or secondary metabolites. Primary metabolites are widely distributed in nature, occurring in one form or another in virtually all organisms. In higher plants such compounds are often concentrated in seeds and vegetative storage organs and are needed for physiological development because of their role in basic cell metabolism.
Plants generally produce many secondary metabolites which are biosynthetically derived from primary metabolites and constitute an important source of micro biocides, pesticides and many pharmaceutical drugs. From a long period of time medicinal plants or their secondary metabolites have been directly or indirectly playing an important role in the human society to combat diseases (Wink et al., 2005).

Secondary metabolites (compounds) have no apparent function in a plant’s primary metabolism, but often have an ecological role, as pollinator attractants, represent chemical adaptations to environmental stresses or serve as chemical defense against micro-organisms, insects and higher predators and even other plants (allelochemics). Secondary metabolites are frequently accumulated by plants in smaller quantities than the primary metabolites (Karuppusamy, 2009; Sathishkumar and Paulsamy, 2009).

In contrast to primary metabolites, they are synthesized in specialized cell types and at distinct developmental stages, making their extraction and purification difficult. As a result, secondary metabolites that are used commercially as biologically active compounds, are generally high value-low volume products than the primary metabolites (e.g. steroids, quinines, alkaloids, terpenoids and flavonoids), which are used in drug manufacture by the pharmaceutical industries. These are generally obtained from plant materials by steam distillation or by extraction with organic or aqueous solvents and the molecular weight are generally less than 2000. Some biologically active plant compounds have found application as drug entities or as model compounds for drug synthesis and semi-synthesis.

A survey of current pharmaceutical use revealed that, of the total prescription drugs dispensed, 25% are plant derived (Farnsworth and Morris, 1976; Ogundipe et al., 1998). Plant compounds are highly varied in structure; many are aromatic substances, most of which are phenols or their oxygen-substituted derivatives. However, there is an increased attention on extracts and biologically active compounds isolated from plant species used in herbal medicine, due to the side effects and the resistance that pathogenic micro-organisms build against the antibiotics (Essawi and Srour, 1999). New compounds inhibiting microorganisms such as benzoin and emetine have been isolated from plants (Cox, 1994). Of the various pharmaceuticals used in modern medicine, aspirin, atropine, ephedrine, digoxin, morphine, quinine, reserpine and tubocurarine serve as examples of drugs discovered through observations of indigenous medical practices (Gilani and Rahman, 2005). Eloff (1999) stated that the antimicrobial compounds from plants may inhibit bacteria by a different mechanism than the presently used antibiotics and may have clinical value in the treatment of resistant microbial strains.

Plant constituents may be isolated and used directly as therapeutic agents or as starting materials for drug synthesis or they may serve as models for pharmacologically active compounds in drug synthesis. The general research methods includes proper selection of medicinal plants, preparation of crude extracts, biological screening, detailed chemo pharmacological investigations, toxicological and clinical studies, standardization and use of active moiety as the lead molecule for drug design (Wink et al., 2005).

2.3 Phyllanthus amarus

*Phyllanthus amarus* is a plant of the family Euphorbiaceae and has about approximately 800 species which are found in tropical and subtropical countries of the world. Traditionally, *Phyllanthus amarus* herb has found its usefulness in the treatment of several health problems.
such as diarrhoea, dysentery, dropsy, jaundice, intermittent fevers, urinogenital disorders, scabies and wounds. Topically, it is used for several skin problems ranging from skin ulcers, sores, swelling and itchiness, wounds, bruises, scabies, ulcers and sores, edematous swellings, tubercular ulcers, ringworm, scabby and crusty lesions. Its effect in excretory system is due to its antiurolithic property and it is used in the treatment of kidney/gallstones, other kidney related problems, appendix inflammation and prostate problems (Khatoon et al., 2004; Sen and Batra, 2013; Ushie et al., 2013). The secondary metabolites present in P. amarus are alkaloids, flavonoids, hydrolysable tannins (Ellagitanins), major lignans, polyphenols, triterpenes, sterols and volatile oil. The main active constituents of P. amarus are lignans (phyllanthin, hypophyllanthin, nirurin niranthin, phyltetralin, nirtetralin etc. (Morton, 1981; Chevallier, 2000; Srivastava et al., 2008; Kassuya et al., 2006; Huang et al., 2003; Maciel et al., 2007; Singh et al., 2009), flavonoids (Foo and Wong, 1992; Londhe et al., 2008;), (Foo, 1995), triterpenes (phyllanthenol, phyllanthenone, phytllantheol etc.) (Maciel et al., 2007; Foo and Wong, 1992), alkaloids (Houghton et al., 1996; Kassuya et al., 2006), sterol (amarosterol-A, amarosterol-B etc.) (Ahmad and Alam, 2003) and volatile oil (linalool, phytol etc.) (Moronkola et al., 2009).

Iranloye et al (2011), investigated the aqueous leaf extract of P. amarus for analgesic and anti-inflammatory activities using both thermal and chemical models of pain assessment in rats. The extract caused a significant (p < 0.05) dose related increased inhibition of the carrageenan-induced paw oedema in the rats. The inhibition produced by 200 mg/kg aqueous extract of P. amarus (70.20%) was significantly higher than that of the reference drug (acetylsalicylic acid). The extract produced a marked analgesic activity by inhibiting both early and late phases of pain stimulus in formalin induced paw licking rats and also a significant and dose related increase in inhibition of the mean tail immersion duration at varying water bath temperature (50, 55 and 60 °C).

Figure 1: Phyllanthus amarus
Azadirachta indica

*Azadirachta indica* is a fast growing, evergreen tree found commonly in India, Africa and America. It is a highly esteemed tree with several beneficial properties and applications, especially known for its incredible therapeutic and ethnomedicinal values for mankind. Moreover, it has antiseptic, antifungal, antibacterial, antipyretic, anti-malaria, anti-diabetic and anti-fertility properties among several other uses (Nok *et al.*, 1993; Natarajan *et al.*, 2003; Fredros *et al.*, 2007; Mbaya *et al.*, 2010). Neem elaborates a vast array of biologically active compounds that are chemically diverse and structurally variable with more than 140 compounds isolated from different parts of the tree (Subapriya and Nagini, 2005).

These compounds have been divided into two major classes: isoprenoids and others (Dev kumar and SukhDev, 1996). The isoprenoids include diterpenoids and triterpenoids containing protomelicains, limonoids, azadirone and its derivatives, gedunin and its derivatives, vilasinin type of compounds and Csecomeliacins such as nimbin, salanin and azadiracthin. The nonisoprenoids include proteins (amino acids) and carbohydrates (polysaccharides), sulphurous compounds, polyphenolics such as flavonoids and their glycosides, dihydrochalcone, coumarin and tannins, aliphatic compounds, etc. (Kraus, 1995; Dev kumar and SukhDev, 1996).

2 MATERIALS AND METHODS
2.1 Sample Collection and Processing

Fresh leaves of *Phyllanthus amarus* and *Azadirachta indica* were collected and identified at the Forestry Research Institute of Nigeria, Oyo State, Nigeria. The leaves were washed properly to remove foreign matter and air dried. The leaves were then grinded to powder with a mechanical grinder, weighed and labeled. The powder was then subjected to various solvent extraction processes.

2.2 Plant extraction using different solvents

Fresh leaves of *P. amarus* and *A. indica* were dried and ground to powder. Extraction and fractionation was carried out using different solvents to determine the antimicrobial activity against the test organisms and control isolates. Extraction was achieved by cold maceration method.

2.2.1 Extraction and Partitioning of crude extracts

2.2.1.1 Aqueous Extraction

Three hundred and fifty grams of powdered *Phyllanthus amarus* and *Azadirachta indica* plant material was macerated via cold extraction by soaking with 1750 ml of distilled water in flat bottomed flasks. The flasks were allowed to stand for seventy two (72) hours at room temperature with occasional stirring at intervals. The extract was filtered using a filter paper (Whatman No.1) and the filtrate was concentrated, evaporated to dryness and weighed.

2.2.1.2 Methanol Extraction

Three hundred and fifty grams of powdered *Phyllanthus amarus* and *Azadirachta indica* plant materials was macerated via cold extraction by soaking with 1750 ml of distilled methanol in flat bottomed flasks. The flasks were allowed to stand for seven days at room temperature with occasional stirring at intervals. The extract was filtered using a filter paper (Whatman No.1) and the filtrate was concentrated at 40°C under reduced pressure using rotavapor (BUCHI Rotavapor R200, Switzerland) and weighed. The crude methanol extract was dissolved in aqueous methanol in a separatory funnel and partitioned with n-hexane, ethyl acetate and chloroform. The fractions were concentrated using rotavapor, weighed and labeled. The fractions were screened for phytochemicals.

Phytochemical Screening

The medicinal and antibacterial effects of medicinal plants are mostly due to the secondary metabolites produced by them, therefore the methods described by Sofowora(1993) and Trease and Evans(1989) were used to screen the crude aqueous and methanolic extracts of *P. amarus* and *A. indica* for the presence of such metabolites. These metabolites include Alkaloids, Tannins, Saponins, Cardiac Glycosides, Flavonoids, Terpenoids and Anthraquinones.

Test for anthraquinones

0.5 g of the extract was boiled with 10 ml of sulphuric acid (H2SO4) and filtered while hot. The filtrate was shaken with 5 ml of chloroform. The chloroform layer was pipetted into another test
tube and 1 ml of dilute ammonia was added. The resulting solution was observed for colour changes.

**Test for terpenoids (Salkowski test)**
To 0.5 g each of the extract was added 2 ml of chloroform. Concentrated H₂SO₄ (3 ml) was carefully added to form a layer. A reddish brown colouration of the interface indicates the presence of terpenoids.

**Test for flavonoids**
Three methods were used to test for flavonoids. First, dilute ammonia (5 ml) was added to a portion of an aqueous filtrate of the extract. Concentrated sulphuric acid (1 ml) was added. A yellow colouration that disappear on standing indicates the presence of flavonoids. Second, a few drops of 1% aluminium solution were added to a portion of the filtrate. A yellow colouration indicates the presence of flavonoids. Third, a portion of the extract was heated with 10 ml of ethyl acetate over a steam bath for 3 min. The mixture was filtered and 4 ml of the filtrate was shaken with 1 ml of dilute ammonia solution. A yellow colouration indicates the presence of flavonoids.

**Test for saponins**
To 0.5 g of extract in a test tube, 5 ml of distilled water was added. The solution was shaken vigorously and observed for a stable persistent froth. The frothing was mixed with 3 drops of olive oil and shaken vigorously after which it was observed for the formation of an emulsion.

**Test for tannins**
0.5 g of the extract was boiled in 10 ml of water in a test tube and then filtered. A few drops of 0.1% ferric chloride was added and observed for brownish green or a blue-black colouration

**Test for alkaloids**
0.5 g of extract was diluted to 10 ml with acid alcohol, boiled and filtered. To 5 ml of the filtrate was added 2 ml of dilute ammonia. 5 ml of chloroform was added and shaken gently to extract the alkaloidal base. The chloroform layer was extracted with 10 ml of acetic acid. This was divided into two portions. Mayer’s reagent was added to one portion and Draggendorff’s reagent to the other. The formation of a cream (with Mayer’s reagent) or reddish brown precipitate (with Draggendorff’s reagent) was regarded as positive for the presence of alkaloids.

**Test for cardiac glycosides (Keller-Killiani test)**
To 0.5 g of extract diluted to 5 ml in water was added 2 ml of glacial acetic acid containing one drop of ferric chloride solution. This was underlayed with 1 ml of concentrated sulphuric acid. A brown ring at the interface indicated the presence of a deoxysugar characteristic of cardenolides. A violet ring may appear below the brown ring, while in the acetic acid layer a greenish ring may form just above the brown ring and gradually spread throughout this layer.

3. RESULTS

3.1 Phytochemical Screening
Table 3.1 shows the result of the qualitative phytochemical screening of the extracts of *Phyllanthus amarus* and *Azadirachta indica* which indicates the presence of alkaloids, flavonoids, saponins, tannins, anthraquinones, terpenoids and cardiac glycosides in varying concentrations within the aqueous and methanol extracts. Flavonoids were abundant in the crude methanolic and aqueous extract of *A.indica* but were absent in the methanolic and aqueous extract of *P.amarus*. Alkaloids were also abundantly present in the crude methanol and aqueous extract of *A.indica* but were significantly absent in the crude methanol and aqueous extract of *P.amarus*. Saponins were slightly and moderately present in the methanol and aqueous crude extract of *P.amarus* while it was slightly present in both the crude methanol and aqueous extract of *A. indica*. Tannins were not detected in the crude methanol extract of *P.amarus* but were moderately present in the aqueous extract while it was slightly and moderately present in the crude aqueous and methanol extract of *A.indica*. Anthraquinones were slightly present in the crude aqueous and methanol extract of both *P.amarus* and *A.indica*. Terpenoids were not detected in the crude methanol extract of *P.amarus* but was slightly detected in the crude aqueous extract and in both the crude methanol and aqueous extract of *A.indica*. Cardiac glycosides were absent in the crude aqueous and methanol extract of *P.amarus* and *A.indica*.

4. DISCUSSION

The phytochemical analysis of plants examines the presence of phytochemicals considered as active medicinal chemical constituents. This study revealed the presence of bioactive constituents present in *Phyllanthus amarus* and *Azadirachta indica*. The qualitative analysis of the aqueous and methanol extracts of both plants showed the varying presence of Alkaloids, Flavonoids, Saponins, Tannins, Anthraquinones, Terpenoids, and Cardiac Glycosides. Alkaloids, Flavonoids and Cardiac Glycosides were absent in both the aqueous and methanol extract of *Phyllanthus amarus*. Tannins and Terpenoids were also absent in the methanolic extract of *Phyllanthus amarus* but were found to be present in the aqueous extract. However, the results showed that Alkaloids and Flavonoids were abundantly present in both the aqueous and methanol extract of *Azadirachta indica* which is similar to the work of. Cardiac Glycosides were found to be absent in both the aqueous and methanol extract of *Azadirachta indica*. The results also showed that the different solvents; ethyl acetate, chloroform, n-hexane used for fractionation possess considerable amounts of bioactive compounds.

5. CONCLUSION

*Azadirachta indica* has become important in the global context today because it offers answers to the major concerns facing mankind. It is a fast-growing evergreen popular tree found commonly in India, Africa and America. As recorded in Table 1, methanolic extract of *A. indica* shows the presence of glycoside having highest concentration, while alkaloids, flavonoids, tannins and sugar having moderate concentration and saponins having low concentration. At the same time, in aqueous extract was found to have maximum number of phytoconstituents in saponins and flavonoid, sugar have low concentration. The Medicinal plants are rich in secondary metabolites which include alkaloids, flavonoids, saponins and related active metabolites which are of great medicinal value and have been extensively used in the drug and pharmaceutical industry. These secondary metabolites are reported to have many biological and therapeutic properties. Recently number of studies had been reported on the phytochemistry of medicinal plants, particularly on the vegetative parts like leaves and stems etc. Alkaloids, flavonoids, glycosides have been reported to exert multiple biological effects like anti-inflammatory, anti-allergic, antioxidant, anti-diabetic, anti-viral and anti-cancer activities, anti-leprosy activities, antimicrobial activity etc. The phytoconstituents are well known for its curative activity against several human problems such as ulcers, swollen liver, malaria, dysentery, diarrhea etc. A variety of herbs and herbal extracts contain different phytochemicals with biological action that can be of valuable
therapeutic index. Much of the protective effect of herbal plants has been attributed by phytochemicals, which are the non-nutrient compounds.
